

## Tutorial 2: Nonlinear Equations

### Bisection and Newton's methods in practice

Use the bisection and Newton methods implemented in the `Roots` package to determine the unique real root of the function

$$f(x) = 4 - 3x + 2x^2 - x^3.$$

To do so, you will have to determine an initial bracketing interval  $[a_0, b_0]$  and an initial guess  $x_0$ . These quantities can be easily read off from a plot of  $f(x)$  over a suitable range of  $x$ -values.

### Newton's method for computing complex square roots

Write a Julia function `square_root(w)` which uses Newton's method to compute complex square roots

$$x + iy = \sqrt{u + iv} \quad \Longleftrightarrow \quad (x + iy)^2 = u + iv.$$

To do so, you must translate the equation on the right into a  $2 \times 2$  system of nonlinear equations  $f(x) = 0$ , manually compute the Jacobian  $\nabla f(x)$  and then implement the Newton iteration

$$x_{k+1} = x_k - \nabla f(x_k)^{-1} f(x_k)$$

in Julia (you can use `df(xk) \ f(xk)` to solve the linear system).

Can you observe the quadratic convergence of Newton's method?

Algorithmic details:

- Use  $(x_0, y_0) = (u, v)$  as initial guess.
- Terminate the iteration once  $|(x + iy)^2 - (u + iv)| \leq 10 \text{eps}() |x + iy|$ .
- Throw an error if the iteration does not terminate after 20 steps.  
You can do so using the command `error("[error message]")`.

Julia hints:

- The imaginary unit is called `im`. (Example: `im^2 -> -1+0im`)
- You can obtain the real and imaginary parts of a complex number `z` using `real(z)` and `imag(z)`, respectively. (Example: `real(1+2im) -> 1`, `imag(1+2im) -> 2`)
